# Weightwise (almost) perfectly balanced functions based on total orders 

Pierrick Méaux<br>Luxembourg university, Luxembourg<br>pierrick.meaux@uni.lu

#### Abstract

The unique design of the FLIP cipher necessitated a generalization of standard cryptographic criteria for Boolean functions used in stream ciphers, prompting a focus on properties specific to subsets of $\mathbb{F}_{2}^{n}$ rather than the entire set. This led to heightened interest in properties related to fixed Hamming weight sets and the corresponding partition of $\mathbb{F}_{2}^{n}$ into $n+1$ such sets. Consequently, the concept of Weightwise Almost Perfectly Balanced (WAPB) functions emerged, which are balanced on each of these sets. Various studies have since proposed WAPB constructions and examined their cryptographic parameters for use in stream cipher filters. In this article, we introduce a general approach to constructing WAPB functions using the concept of order, which simplifies implementation and enhances cryptographic strength. We present two new constructions: a recursive method employing multiple orders on binary strings, and another utilizing just two orders. We establish lower bounds for nonlinearity and weightwise nonlinearities within these classes. By instantiating specific orders, we demonstrate that some achieve minimal algebraic immunity, while others provide functions with guaranteed optimal algebraic immunity. Experimental results in 8 and 16 variables indicate that using orders based on field representation significantly outperforms other methods in terms of both global and weightwise algebraic immunity and nonlinearity. Additionally, we extend the recursive construction to create WAPB functions for any value of $n$, with experiments in 10,12 , and 14 variables confirming that these order-based functions exhibit robust cryptographic parameters. In particular, those based on field orders display optimal degrees and algebraic immunity, and strong weightwise nonlinearities and algebraic immunities.

Keywords: Boolean functions, Weightwise perfectly balanced functions, Cryptographic criteria.

## 1 Introduction

With the design of FLIP [MJSC16], established cryptographic criteria for Boolean functions-traditionally used to assess the security of filtered Linear Feedback Shift Register (LFSR), combined LFSR, or more complex stream cipher designs-no longer apply. In the context of this cipher, the relevant properties of the Boolean function used as a filter to determine security are not based on the entire $\mathbb{F}_{2}^{n}$ but only on a specific identified subset. This change has necessitated the generalization of standard attacks and the establishment of new criteria for subsets and specific partitions of $\mathbb{F}_{2}^{n}$, beginning with the study of restricted criteria for Boolean functions [CMR17].

In the case of FLIP, the input to the filtering function always has a fixed, known Hamming weight, thus tailoring attacks to this specificity enhances their effectiveness. This adaptation exemplifies a broader phenomenon where additional information about a cipher's internal values can significantly simplify attacks, as seen in multiple contexts like (algebraic) side-channel attacks [RS09] or lattice reduction with side information [DDGR20]. From the FLIP study, the focus has been on the partition of the Boolean hypercube into $n+1$ slices, defined as sets with elements of the same Hamming weight $\mathrm{E}_{k, n}=\left\{x \in \mathbb{F}_{2}^{n} \mid \mathrm{w}_{\mathrm{H}}(x)=k\right\}$ for $k \in[0, n]$. Notably, the Hamming weight of an intermediate value is also commonly leveraged as leakage in side channel attacks, e.g. [JO05, Sta10, DMMS20], although a leakage with an approximate Hamming weight is considered more realistic e.g. [ORSW12, BFG14, $\mathrm{HMM}^{+}$23].

A fundamental security criterion for a Boolean function is balancedness, the function is balanced if it outputs 1 for half of the inputs and 0 for the other half, to prevent statistical biases exploitable by various attacks. Functions that are balanced over each slice were introduced in [CMR17] as Weightwise
(Almost) Perfectly Balanced (WAPB) functions. The term "almost" differentiates cases where $n$ is a power of two-here, the function is perfectly balanced on all slices except for those with $k$ equal to 0 or 1 . For other values of $n$, where many slices have an odd cardinality, the functions output 1 one more (or one less) time than 0 . Since 2017, multiple studies have focused on developing new constructions of W(A)PB functions with improved parameters for use as filter functions. These efforts include enhancing globally recognized cryptographic parameters such as algebraic degree, Algebraic Immunity (AI), and nonlinearity, as well as important criteria on the slices, like weightwise nonlinearities and weightwise algebraic immunity.

We provide a concise overview of the main families of WAPB functions showcased in previous studies, noting that most focus primarily on WPB functions. Initially, a recursive approach for both WPB and WAPB was introduced in [CMR17], followed by a secondary construction. In 2019, the work in [LM19] (and later [MSLZ22]) utilized field representations to develop WPB functions that are 2-rotation symmetric and achieve high weightwise nonlinearities. The construction in [TL19] (and an adaptation with better weightwise nonlinearities in [MSL21]) compare the weight of inputs split into two halves, resulting in constructions affine equivalent to the majority function, thus reaching optimal algebraic immunity. The construction in [MS21] start from a linear or quadratic function near WPB status, and modify their algebraic normal form to achieve balancedness over all slices. This methodology was later expanded to generate WAPB functions from functions of low degrees, as detailed in [LS20, GS22, ZS23, ZJZQ23, ZLC ${ }^{+}$23]. Additional methods for constructing WAPB functions have been introduced, utilizing direct sums [ZS22] or Sieghentaler's construction and addition of symmetric function [GM22b]. Furthermore, various families have been developed by slightly altering the support of non-WPB functions, as reported in studies focusing on the distribution of cryptographic parameters of WPB functions, particularly on weightwise nonlinearity [GM22a], nonlinearity [GM23c], and algebraic immunity [GM23a]. Recent efforts have also employed evolutionary algorithms to enhance the parameters of WPB functions, concentrating on weightwise nonlinearities [MPJ ${ }^{+}$22, $\mathrm{YCL}^{+}$23], and on nonlinearity [MKCL22]. Additional constructions and properties of restricted criteria have been explored in a range of works (a non-exhaustive list includes [MZD19, DM23, GM23b, DM24]).

In this article, we explore a novel general approach for WAPB, where the input is split in two halves, and the function value is determined by an ordering on binary vectors of length $n / 2$. This method simplifies the implementation of WPB functions and offers superior parameters compared to previously exhibited functions.

Firstly, we introduce two novel constructions of WPB functions: a recursive construction employing multiple orders for binary vectors (one for each power of 2 between 2 and $n / 2$ for an $n$-variable WPB function) and a second, simpler construction involving just two orders. We quantify the number of functions within these categories and examine their nonlinearities. We establish a lower bound for the nonlinearity of any function from these families-at least half that of a bent function-and we derive lower bounds for the weightwise nonlinearities across the full classes.

Then, we instantiate the constructions with specific orders. We implement prevalent orders-Lexicographic and Cool-alongside orders that respect the Hamming weight (termed weightwise order) and others based on the field representation of $\mathbb{F}_{2^{t}}$. We examine the algebraic immunity of these constructions, proving that those based on the lexicographic order achieve the minimal AI for WPB functions, whereas weightwise orders result in optimal AI. We provide experimental results detailing the relevant parameters of WPB functions in 8 and 16 variables for these different orders, where we observe that the new constructions using the field representation outperform the other ones in both algebraic immunity and nonlinearity, both globally and weightwise.

Finally, we extend the recursive construction to furnish WAPB functions for all $n$. We report outcomes for global parameters-such as resilience order, nonlinearity, degree, and algebraic immunity-as well as weightwise parameters, specifically weightwise nonlinearities and algebraic immunities. Experimentally, we determine these parameters for functions in 10,12 , and 14 variables. Similar to WPB functions, this study underscores that order-based WAPB functions can exhibit robust cryptographic parameters. Notably, those based on field orders showcase optimal degrees, optimal algebraic immunity, and strong weightwise algebraic immunities and nonlinearities.

## 2 Preliminaries

For readability, we use the notation + instead of $\oplus$ to denote the addition in $\mathbb{F}_{2}$, and $\sum$ instead of $\oplus$. In addition to classic notations, we denote by $[a, b]$ the subset of all integers between $a$ and $b:\{a, a+1, \ldots, b\}$. For a vector $v \in \mathbb{F}_{2}^{n}$ we use $\mathbf{w}_{\mathbf{H}}(v)$ to denote its Hamming weight $\mathbf{w}_{\mathbf{H}}(v)=\left|\left\{i \in[1, n] \mid v_{i}=1\right\}\right|$. For two vectors $v$ and $w$ in $\mathbb{F}_{2}^{n}$ we denote by $\mathrm{d}_{\mathrm{H}}(v, w)$ the Hamming distance between $v$ and $w$, that is, $\mathrm{d}_{\mathrm{H}}(v, w)=\mathrm{w}_{\mathrm{H}}(v+w)$. For two functions $f$ and $g$ we denote by $\mathrm{d}_{\mathrm{H}}(f, g)$ the Hamming distance between their vectors of values.

### 2.1 Boolean functions, cryptographic criteria, and weightwise properties

In this section, we recall fundamental concepts concerning Boolean functions and their weightwise properties, which are utilized throughout this article. For a more comprehensive introduction to Boolean functions and their cryptographic parameters, we recommend consulting the book by Carlet [Car21], and for insights into weightwise properties-also known as properties on the slices-the article by [CMR17]. We denote by $\mathrm{E}_{k, n}$ the set $\left\{x \in \mathbb{F}_{2}^{n} \mid \mathrm{w}_{\mathrm{H}}(x)=k\right\}$ for $k \in[0, n]$, referring to it as a slice of the Boolean hypercube (of dimension $n$ ). Consequently, the Boolean hypercube is divided into $n+1$ slices, where the elements share the same Hamming weight.

Definition 1 (Boolean Function). A Boolean function $f$ in $n$ variables is a function from $\mathbb{F}_{2}^{n}$ to $\mathbb{F}_{2}$. The set of all Boolean functions in $n$ variables is denoted by $\mathcal{B}_{n}$.

When a property or a definition is restricted to a slice, we denote it by using the subscript $k$. For example, for an $n$-variable Boolean function $f$ we denote its support $\operatorname{supp}(f)=\left\{x \in \mathbb{F}_{2}^{n} \mid f(x)=1\right\}$. Furthermore, we denote by $\operatorname{supp}_{k}(f)$ the support of $f$ restricted to a slice, which is defined as $\operatorname{supp}(f) \cap \mathrm{E}_{k, n}$.

Definition 2 (Balancedness). A Boolean function $f \in \mathcal{B}_{n}$ is called balanced if $|\operatorname{supp}(f)|=2^{n-1}=$ $|\operatorname{supp}(f+1)|$.

For $k \in[0, n]$ the function is said balanced on the slice $k$ if $\left|\left|\operatorname{supp}_{k}(f)\right|-\left|\operatorname{supp}_{k}(f+1)\right|\right| \leq 1$. In particular when $\left|\mathrm{E}_{k, n}\right|$ is even $\left|\operatorname{supp}_{k}(f)\right|=\left|\operatorname{supp}_{k}(f+1)\right|=\left|\mathrm{E}_{k, n}\right| / 2$.

Using the notion of restricted balancedness we can define the weightwise (almost) perfectly balanced functions, the focus of our work.

Definition 3 (Weightwise (Almost) Perfectly Balanced Function (WPB and WAPB)). Let $m \in \mathbb{N}^{*}$ and $f$ be a Boolean function in $n=2^{m}$ variables. It will be called weightwise perfectly balanced (WPB) if, for every $k \in[1, n-1], f$ is balanced on the slice $k$, that is $\forall k \in[1, n-1]$, $\left|\operatorname{supp}_{k}(f)\right|=\binom{n}{k} / 2$, and:

$$
f(0, \cdots, 0)=0, \quad \text { and } f(1, \cdots, 1)=1 .
$$

The set of WPB functions in $2^{m}$ variables is denoted $\mathcal{W P B} \mathcal{B}_{m}$.
When $n$ is not a power of 2 , other weights than $k=0$ and $n$ can lead to slices of odd cardinality, we call $f \in \mathcal{B}_{n}$ weightwise almost perfectly balanced (WAPB) if:

$$
\left|\operatorname{supp}_{k}(f)\right|= \begin{cases}\left|\mathrm{E}_{k, n}\right| / 2 & \text { if }\left|\mathrm{E}_{k, n}\right| \text { is even } \\ \left(\left|\mathrm{E}_{k, n}\right| \pm 1\right) / 2 & \text { if }\left|\mathrm{E}_{k, n}\right| \text { is odd }\end{cases}
$$

The set of WAPB functions in $n$ variables is denoted $\mathcal{W} \mathcal{A P} \mathcal{B}_{n}$.
We define additional crucial concepts for studying Boolean functions, namely the algebraic normal form and the Walsh transform. Subsequently, we introduce key cryptographic criteria for these functions, including algebraic immunity (both general and weightwise) and nonlinearity (both general and weightwise).

Definition 4 (Algebraic Normal Form (ANF) and degree). We call Algebraic Normal Form of a Boolean function $f$ its $n$-variable polynomial representation over $\mathbb{F}_{2}$ (i.e. belonging to $\mathbb{F}_{2}\left[x_{1}, \ldots, x_{n}\right] /\left(x_{1}^{2}+\right.$ $\left.x_{1}, \ldots, x_{n}^{2}+x_{n}\right)$ ):

$$
f\left(x_{1}, \ldots, x_{n}\right)=\sum_{I \subseteq[1, n]} a_{I}\left(\prod_{i \in I} x_{i}\right)
$$

where $a_{I} \in \mathbb{F}_{2}$. The (algebraic) degree of $f$, denoted $\operatorname{deg}(f)$ is:

$$
\operatorname{deg}(f)=\max _{I \subseteq[1, n]}\left\{|I| \mid a_{I}=1\right\} \text { if } f \text { is not null, } 0 \text { otherwise } .
$$

Definition 5 (Algebraic immunity and restricted algebraic immunity). The algebraic immunity of $a$ Boolean function $f \in \mathcal{B}_{n}$, denoted as $\mathrm{Al}(f)$, is defined as:

$$
\operatorname{Al}(f)=\min _{g \neq 0}\{\operatorname{deg}(g) \mid f g=0 \text { or }(f+1) g=0\}
$$

where $\operatorname{deg}(g)$ is the algebraic degree of $g$. The function $g$ is called an annihilator of $f($ or $f+1)$.
The restricted algebraic immunity of a Boolean function $f \in \mathcal{B}_{n}$ on the set $S \subset \mathbb{F}_{2}^{n}$, denoted as $\mathrm{Al}_{S}(f)$, is defined as:

$$
\mathrm{Al}_{S}(f)=\min _{g \neq 0 \text { over } S}\{\operatorname{deg}(g) \mid f g=0 \text { or }(f+1) g=0\}
$$

For $S=\mathrm{E}_{k, n}$ we denote $\mathrm{AI}_{\mathrm{E}_{k, n}}(f)$ by $\mathrm{AI}_{k}(f)$ and call it weightwise algebraic immunity.
Definition 6 (Walsh transform and restricted Walsh transform). Let $f \in \mathcal{B}_{n}$ be a Boolean function, its Walsh transform $W_{f}$ at $a \in \mathbb{F}_{2}^{n}$ is defined as:

$$
W_{f}(a):=\sum_{x \in \mathbb{F}_{2}^{n}}(-1)^{f(x)+a \cdot x}
$$

Let $f \in \mathcal{B}_{n}, S \subset \mathbb{F}_{2}^{n}$, its Walsh transform restricted to $S$ at $a \in \mathbb{F}_{2}^{n}$ is defined as:

$$
W_{f, S}(a):=\sum_{x \in S}(-1)^{f(x)+a x}
$$

For $S=\mathrm{E}_{k, n}$ we denote $W_{f, \mathrm{E}_{k, n}}(a)$ by $\mathcal{W}_{f, k}(a)$.

Property 1 (WAPB functions and restricted Walsh transform). Let $n \in \mathbb{N}^{*}, f \in \mathcal{B}_{n}$ is WAPB if and only if:

$$
\forall k \in[0, n], \mathcal{W}_{f, k}\left(0_{n}\right)= \begin{cases}0 & \text { if }\left|\mathrm{E}_{k, n}\right| \text { is even } \\ \pm 1 & \text { if }\left|\mathrm{E}_{k, n}\right| \text { is odd }\end{cases}
$$

If $n=2^{m}$ with $m \in \mathbb{N}^{*}, f \in \mathcal{B}_{n}$ is WPB if and only if:

$$
\mathcal{W}_{f, 0}\left(0_{n}\right)=1, \quad \mathcal{W}_{f, n}\left(0_{n}\right)=-1, \text { and } \quad \forall k \in[1, n-1] \mathcal{W}_{f, k}\left(0_{n}\right)=0
$$

Definition 7 (Nonlinearity and weightwise nonlinearity). The nonlinearity $\mathrm{NL}(f)$ of a Boolean function $f \in \mathcal{B}_{n}$, where $n$ is a positive integer, is the minimum Hamming distance between $f$ and all the affine functions in $\mathcal{B}_{n}$ :

$$
\mathrm{NL}(f)=\min _{g, \operatorname{deg}(g) \leq 1}\left\{\mathrm{~d}_{\mathrm{H}}(f, g)\right\},
$$

where $g(x)=a \cdot x+\varepsilon, a \in \mathbb{F}_{2}^{n}, \varepsilon \in \mathbb{F}_{2}$.
The nonlinearity can also be defined from the Walsh transform:

$$
\mathrm{NL}(f)=2^{n-1}-\frac{1}{2} \max _{a \in \mathbb{F}_{2}^{n}}\left|W_{f}(a)\right| .
$$

For $k \in[0, n]$ we denote $\mathrm{NL}_{k}$ the nonlinearity on the slice $k$, the minimum Hamming distance between $f$ restricted to $\mathrm{E}_{k, n}$ and the restrictions to $\mathrm{E}_{k, n}$ of affine functions over $\mathbb{F}_{2}^{n}$. Accordingly:

$$
\mathrm{NL}_{k}(f)=\min _{g, \operatorname{deg}(g) \leq 1}\left|\operatorname{supp}_{k}(f+g)\right|
$$

Property 2 (Nonlinearity on the slice, adapted from [CMR17], Proposition 6). Let $n \in \mathbb{N}^{*}, k \in[0, n]$, for every $n$-variable Boolean function $f$ over $\mathrm{E}_{k, n}$ :

$$
\mathrm{NL}_{k}(f)=\frac{\left|\mathrm{E}_{k, n}\right|}{2}-\frac{\max _{a \in \mathbb{F}_{2}^{n}}\left|\mathcal{W}_{f, k}(a)\right|}{2} .
$$

### 2.2 Orders

In this part we recall the notion of order. This notion is the key concept for the new constructions of WPB and WAPB functions we present in the article.

## Definition 8 (Order).

A binary relation $\preceq$ on a set $X$ is called partial order if $\preceq$ is reflexive, transitive and antisymmetric. Moreover, $\preceq$ is a total order if for all $a, b \in X$ it holds $a \preceq b$ or $b \preceq a$.

We give two examples of orders on $n$-length binary string, more examples can be found in e.g. [SW12] that also considers order on sets of fixed Hamming weight:

- Lexicographic, given $a, b \in \mathbb{F}_{2}^{n}$ as $a=a_{1}, \ldots, a_{n}$ and $b=b_{1}, \ldots, b_{n}, a \preceq b$ if and only if $a_{i}<b_{i}$ on the first index $i \in[1, n]$ such that $a_{i} \neq b_{i}$, or $a=b$.
- Cool [RW09], a first element of $\mathbb{F}_{2}^{n}$ is chosen and a successor rule is used to determine the following element, allowing to generate the $2^{n}$ elements with no repetition. The successor rule for $a_{1}, a_{2}, \ldots, a_{n}$ is: Let $i$ be the minimum value such that $\left(a_{i}, a_{i+1}\right)=(1,0)$ and $i>1$. If $i$ exists, then rotate $i+1$ bits, otherwise flip $a_{1}$ and then rotate $n$ bits.

### 2.3 Krawtchouk polynomials

We use Krawtchouk polynomials and some of their properties to prove one of our results, we give the necessary preliminaries here and refer to e.g. [MS78] for more details.

Definition 9 (Krawtchouk Polynomials). The Krawtchouk polynomial of degree $k$, with $0 \leq k \leq n$ is given by: $\mathrm{K}_{k}(\ell, n)=\sum_{j=0}^{k}(-1)^{j}\binom{\ell}{j}\binom{n-\ell}{k-j}$.

Property 3 (Krawtchouk polynomials relation). Let $n \in \mathbb{N}^{*}$ and $k \in[0, n]$, the following hold: $\mathrm{K}_{k}(\ell, n)$ is the value of the restricted Walsh transform on $\mathrm{E}_{k, n}$ of any $n$ variable linear function $a \cdot \ell$ such that $\mathrm{w}_{\mathrm{H}}(a)=\ell$.

Property 4 (Vandermonde Convolution). Let $a, b, c \in \mathbb{N}$, then:

$$
\binom{a+c}{b}=\sum_{j=0}^{b}\binom{c}{b-j}\binom{a}{j} .
$$

### 2.4 Tang-Liu WPB functions

We recall the construction of WPB functions from Tang and Liu [TL19] and one on its properties. We use these results to prove the algebraic immunity of special cases of our main constructions.

Definition 10 (TL WPB construction (adapted from [TL19], Construction 1 )). Let $m \in \mathbb{N}^{*}$ and $n=$ $2^{m} \geq 4$ be an integer. A TL WPB Boolean function $h$ on $n$-variable is such that

- $h\left(0_{n}\right)=0$ and $h\left(1_{n}\right)=1$
- $h(x, y)=0$ if $\mathrm{w}_{\mathrm{H}}(x)<\mathrm{w}_{\mathrm{H}}(y)$.
- $h(x, y)=1$ if $\mathrm{w}_{\mathrm{H}}(x)>\mathrm{w}_{\mathrm{H}}(y)$.
- the cardinality of $U_{i}=\operatorname{supp}(h) \cap\left\{(x, y) \in \mathbb{F}_{2}^{2^{m-1}} \times \mathbb{F}_{2}^{2^{m-1}}: \mathrm{w}_{\mathbf{H}}(x)=\mathrm{w}_{\mathbf{H}}(y)=j\right\}$ is exactly $\binom{2^{m-1}}{j}^{2} / 2$ for all $0<j<2^{m-1}$.

Remark 1. Despite Definition 10 may appear quite different respect the original paper, it is equivalent when considering the restriction on $n$ to be a power of two, and the values in $0_{n}$ and $1_{n}$ imposed by Definition 3 .

Property 5 (TL WPB functions properties [TL19]). Let $m \in \mathbb{N}^{*}$ and $n=2^{m}$, a $n$-variable TL function $h_{n}$ has optimal algebraic immunity $\mathrm{Al}\left(h_{n}\right)=\frac{n}{2}$.

## 3 Constructions based on total orders

We present our two main constructions of weightwise perfectly balanced functions based on the notion of order. First, we introduce Construction 1, which utilizes an order for each bit length ranging from 2 to $2^{m-1}$ and is constructed recursively. Then, we present Construction 2, which is defined using only two orders. Finally, we analyze the nonlinearities of the WPB functions generated by these constructions. We provide a lower bound on the nonlinearity and weightwise nonlinearities of all functions within these families.

### 3.1 Recursive construction

Definition 11 (Construction 1). Let $m \in \mathbb{N}^{*}$, and for $i \in[0, m-1] \preceq_{i}$ be a total order on the set of $2^{i}$-length binary string.

Let $f_{m}$ be the $2^{m}$-variable function defined as:

$$
\begin{aligned}
& -f_{m}\left(0_{2^{m}}\right)=0, f_{m}\left(1_{2^{m}}\right)=1, \\
& -
\end{aligned}
$$

$$
f_{m}(x, y)= \begin{cases}f_{m-1}(x) & \text { if } x=y \\ 0 & \text { if } x \prec_{m-1} y \\ 1 & \text { if } y \prec_{m-1} x\end{cases}
$$

where $x, y \in \mathbb{F}_{2}^{m-1}$.
Theorem 1. Let $f_{m}$ defined as in Definition 11. $f_{m}$ is weightwise perfectly balanced.
Proof. We prove it by recursion. First, $f_{1}(x, y)$ takes the value 0 in $(0,0)$ and 1 in $(1,1)$ since by definition $f_{m}\left(0_{2^{m}}\right)=0$ and $f_{m}\left(1_{2^{m}}\right)=1$. For the two elements $(x, y) \in \mathbb{F}_{2}^{m}$ such that $x \neq y$, that is $\mathrm{E}_{1, n}$, it holds $0 \prec_{0} 1$ or $1 \prec_{0} 0$, hence $f_{1}$ takes the value 1 on exactly one of them. Consequently $f_{1}$ is WPB, which proves the basis of the recursion.

Then, if for $j \in[1, m-1] f_{j}$ is WPB we show that $f_{j+1}$ is also WPB. We denote $n=2^{j+1}, f_{j+1}(x, y)$ takes the value 0 in $\left(0_{n}\right)$ and 1 in $\left(1_{n}\right)$ by definition. Then, for any weight $k \in[1, n-1]$ the set $\mathrm{E}_{k, n}$ can be split in the two sets $A=\left\{(x, y) \in \mathrm{E}_{k, n} \mid x=y\right\}$ and $B=\left\{(x, y) \in \mathrm{E}_{k, n} \mid x \neq y\right\}$. On the set $A$, $f_{j+1}(x, y)$ takes the value of $f_{j}(x)$, and since $\left\{x \in \mathbb{F}_{2}^{n / 2} \mid(x, y) \in A\right\}=\mathrm{E}_{k / 2, n / 2}$, the weightwise perfect balancedness of $f_{j}$ implies the balancedness of $f_{j+1}$ on $A$. Finally, the set $B$ can be split in pairs $(x, y)$ and $(y, x)$ (since all elements of $B$ are such that $x \neq y$ ). For each pair, either $x \prec_{j} y$ or $y \prec_{j} x$ hence $f_{j+1}(x, y)=1+f_{j+1}(y, x)$. Accordingly, $f_{j+1}$ is balanced on each of these pairs, hence on $B$, and therefore on the full slice $\mathrm{E}_{k, n}$. It allows to conclude the proof by recursion, $f_{m}$ is WPB.

Proposition 1. Let $m \in \mathbb{N}^{*}$ and, the number $\mathcal{C}_{m}$ of $2^{m}$-variable WPB functions from the family of Definition 11 is:

$$
\mathcal{C}_{m}=\prod_{i=0}^{m-1} 2^{2^{i}!.}
$$

Proof. First, we note that if two functions $f$ and $g$ from the family are defined with a different order for $i$ in $[0, m-1]$ there exist two elements $x$ and $y$ in $\mathbb{F}_{2}^{2^{i}}$ such that $x \prec_{f, i} y$ and $y \prec_{g, i} x$ (where the subscript $f$ or $g$ indicate the order used in the definition of $f$ or $g$ respectively). Then, by Definition $11 f(x, y)=0$ and $g(x, y)=1$, hence $f$ and $g$ are different functions. Therefore, the number of different WPB functions from this family if the product over $m$ of the number of total orders over binary strings of length $2^{i-1}$. Since there are $n$ ! possible total orders on a set of size $n$, it gives the final result: $\prod_{i=0}^{m-1} 2^{2^{2}}$ !.

### 3.2 Construction based on two orders

Definition 12 (Construction 2). Let $m \in \mathbb{N}^{*}$, and $\preceq$ be a total order on the set of $2^{m-1}$-length binary string. Let $\preceq^{\prime}$ be a total order on the set of $2^{m-1}$-length binary string such that for all $k \in\left[1,2^{m-1}-1\right]$
exactly half of the elements of Hamming weight $k$ are in the smallest half. We denote $u$ the $2^{m-2}$-th element in the order $\preceq^{\prime}$.

Let $g_{m}$ be the $2^{m}$-variable function defined as:

- $g_{m}\left(0_{2^{m}}\right)=0, g_{m}\left(1_{2^{m}}\right)=1$,

$$
g_{m}(x, y)= \begin{cases}0 & \text { if } x \prec y, \\ 1 & \text { if } y \prec x, \\ 0 \text { if } x \preceq^{\prime} u, 1 \text { otherwise } & \text { if } x=y,\end{cases}
$$

where $x, y \in \mathbb{F}_{2}^{m-1}$.
Theorem 2. Let $f_{m}$ as defined in Definition 12. $f_{m}$ is weightwise perfectly balanced.
Proof. We denote $n=2^{m}$. By definition $g_{m}\left(0_{2^{m}}\right)=0$ and $g_{m}\left(1_{2^{m}}\right)=1$, so we focus on the balancedness of $g_{m}$ on the slices $\mathrm{E}_{k, n}$ for $k \in[1, n-1]$. Each slice $\mathrm{E}_{k, n}$ can be written as $A \cup B$ where $A$ is the set of elements such that $x=y$, that is $A=\left\{(x, x) \mid x \in \mathbb{F}_{2}^{n / 2}\right\} \cap \mathrm{E}_{k, n}$, and $B$ is the set of elements such that $x \neq y$, that is $B=\left\{(x, y) \mid x, y \in \mathbb{F}_{2}^{n / 2}, x \neq y\right\} \cap \mathrm{E}_{k, n}$. By construction $A \cap B=\emptyset$.

First, we show that $g_{m}$ is balanced over $A$. We remark that $|A|=\left|\mathrm{E}_{k / 2, n / 2}\right|$ and more precisely $\{x \mid(x, x) \in A\}=\mathrm{E}_{k / 2, n / 2}$. By definition of $\preceq^{\prime}$ we have $\left|\left\{x \in \mathrm{E}_{k / 2, n / 2} \mid x \preceq^{\prime} u\right\}\right|=\left|\mathrm{E}_{k / 2, n / 2}\right| / 2$, hence $g_{m}$ is balanced on $A$.

Then, we prove the balancedness on $B$. $B$ can be partitioned into set of pairs $(x, y)$ and $(y, x)$ and since $x \prec y$ or $y \prec x$ since $x \neq y, g_{m}$ is balanced on all the pairs and therefore on all $B$. Finally, $g_{m}$ is balanced on $A \cup B=\mathrm{E}_{k, n}$ for all $k \in[1, n-1]$ which allows to conclude $g_{m}$ is WPB.

Proposition 2. Let $m \in \mathbb{N}^{*}$, the number $\mathcal{D}_{m}$ of $2^{m}$-variable WPB functions from the family of Definition 12 is:

$$
\mathcal{D}_{m}=2^{2^{m-1}}!\times \prod_{k=1}^{2^{m-1}-1}\left(\begin{array}{c}
2^{m-1} k \\
k \\
\frac{1}{2}\binom{2^{m-1}}{k}
\end{array}\right)
$$

Proof. First, using the same argument as for Proposition 1, a different order for $\preceq$ gives a different function. Then, two functions $f$ and $g$ with only $\preceq^{\prime}$ different can still be the same function if and only if for each $k \in[1, n / 2-1]$ (where $n=2^{m}$ ) the same half of $\mathrm{E}_{k, n / 2}$ is in the smallest half. Indeed, if for all $k \in$ $[1, n / 2-1]$, the sets $\left\{x \in \mathrm{E}_{k, n / 2} \mid x \preceq_{f}^{\prime} u_{f}\right\}$ and $\left\{x \in \mathrm{E}_{k, n / 2} \mid x \preceq_{g}^{\prime} u_{g}\right\}$ are equal then $f(x, x)=g(x, x)$ for all $x \in \mathbb{F}_{2}^{n / 2}$. And since we assumed $\preceq_{f}=\preceq_{g}$, for all $(x, y) \in \mathbb{F}_{2}^{n} \mid x \neq y$ we have $f(x, y)=g(x, y)$ therefore $f=g$. Conversely, if there exists $k \in[1, n / 2-1]$ such that $x \in \mathrm{E}_{k, n}$ satisfies $x \preceq_{f}^{\prime} u_{f}$ and $x \swarrow_{g}^{\prime} u_{g}$ (without loss of generality) then $f(x, x)=0$ and $g(x, x)=1$, proving that $f \neq g$.

Finally, we derive the number of different functions, combining the number of different total order on binary strings of length $2^{m-1}$ and the number of partitions of $\mathrm{E}_{k, 2^{m-1}}$ in two parts of same size:

$$
\mathcal{D}_{m}=2^{2^{m-1}}!\times \prod_{k=1}^{2^{m-1}-1}\left(\begin{array}{c}
2^{2^{m-1}} \\
k \\
\frac{1}{2}\binom{2^{m-1}}{k}
\end{array}\right) .
$$

We study the nonlinearity and algebraic immunity of these families. First, we show a lower bound on the nonlinearity of any function from the two constructions. Then we give a lower bound on the weightwise nonlinearity of the WPB constructions in terms of Krawtchouk polynomials. Finally we address the algebraic immunity of the first construction in Section 4 , exhibiting WPB functions with minimal and maximal AI.

### 3.3 A nonlinearity lower bound

Theorem 3. Let $m \in \mathbb{N}^{*}, n=2^{m}$ and $f$ be a function from the constructions of Definition 11 or Definition [12. then:

$$
\mathrm{NL}(f) \geq 2^{n-2}-2^{n / 2-1}
$$

Proof. We compute the Walsh transform of $f$. For all $c \in \mathbb{F}_{2}^{n}$ :

$$
\begin{aligned}
W_{f}(c) & =\sum_{z \in \mathbb{F}_{2}^{n}}(-1)^{f(z)+c z} \\
& =\sum_{x \in \mathbb{F}_{2}^{n / 2}}(-1)^{f(x, x)+(a+b) x}+\sum_{x \in \mathbb{F}_{2}^{n / 2}, y \in \mathbb{F}_{2}^{n / 2} \backslash\{x\}}(-1)^{f(x, y)+a x+b y},
\end{aligned}
$$

where $(a, b)=c$, that is $a$ denotes the first $n / 2$ bits of $c$ and $b$ denotes the second half.
First, we can bound the absolute value of the first term: $\left|\sum_{x \in \mathbb{F}_{2}^{n / 2}}(-1)^{f(x, x)+(a+b) x}\right| \leq 2^{n / 2}$. Then, we rewrite the second term:

$$
\begin{aligned}
A=\sum_{x \in \mathbb{F}_{2}^{n / 2}, y \in \mathbb{F}_{2}^{n / 2} \backslash\{x\}}(-1)^{f(x, y)+a x+b y} & =\frac{1}{2}\left(\sum_{\substack{x \in \mathbb{F}^{n / 2} \\
y \in \mathbb{F}_{2}^{n / 2} \backslash\{x\}}}(-1)^{f(x, y)+a x+b y}+\sum_{\substack{x \in \mathbb{F}^{n / 2} \\
y \in \mathbb{R}_{2}^{n / 2} \backslash\{x\}}}(-1)^{f(x, y)+a x+b y}\right) \\
& =\frac{1}{2} \sum_{x \in \mathbb{F}_{2}^{n / 2}, y \in \mathbb{F}_{2}^{n / 2} \backslash\{x\}}\left((-1)^{f(x, y)+a x+b y}+(-1)^{f(y, x)+a y+b x}\right) \\
& =\frac{1}{2} \sum_{x \in \mathbb{F}_{2}^{n / 2}, y \in \mathbb{F}_{2}^{n / 2} \backslash\{x\}}(-1)^{f(x, y)}\left((-1)^{a x+b y}-(-1)^{a y+b x}\right) .
\end{aligned}
$$

Then, to bound $|A|$, we determine the cardinal of the set $S=\left\{x \in \mathbb{F}_{2}^{n / 2}, y \in \mathbb{F}_{2}^{n / 2} \backslash\{x\} \mid(-1)^{a x+b y}-\right.$ $\left.(-1)^{a y+b x}=0\right\}$. The condition $(-1)^{a x+b y}-(-1)^{a y+b x}=0$ is equivalent to $a x+b y=a y+b x(\bmod 2)$, that is $(a+b)(x+y)=0(\bmod 2)$. First, note that if $a=b$ then $|S|=\left|\left\{x \in \mathbb{F}_{2}^{n / 2}, y \in \mathbb{F}_{2}^{n / 2} \backslash\{x\}\right\}\right|=$ $2^{n / 2} \cdot\left(2^{n / 2}-1\right)$. Hence we focus on the case $d=a+b \neq 0_{n / 2}$.

The addition by a constant $y \in \mathbb{F}_{2}^{\ell}, \psi_{y}$, defined by $\psi_{y}(x)=x+y$ (for $x \in \mathbb{F}_{2}^{\ell}$ ) is a bijection over $\mathbb{F}_{2}^{\ell}$. Then, the image of $\psi_{y}(x)$ for $x \in \mathbb{F}_{2}^{\ell} \backslash\{y\}$ is $\mathbb{F}_{2}^{\ell} \backslash\left\{0_{\ell}\right\}$. Accordingly, the sum $(x+y)$ such that $x \in \mathbb{F}_{2}^{\ell}, y \in \mathbb{F}_{2}^{\ell} \backslash\{x\}$ takes each element of $\mathbb{F}_{2}^{\ell} \backslash\left\{0_{\ell}\right\}$ exactly $2^{\ell}$ times. Since for $d \neq 0_{\ell}$ we have $\left|\left\{x \in \mathbb{F}_{2}^{\ell} \mid d \cdot x=0\right\}\right|=2^{\ell-1}$ and $d \cdot 0_{\ell}=0$ we obtain $|S|=2^{n / 2}\left(2^{n / 2-1}-1\right)=2^{n-1}-2^{n / 2}$. It allows to
bound $|A|$ :

$$
\begin{aligned}
|A| & =\left|\frac{1}{2} \sum_{\substack{x \in \mathbb{F}_{2}^{n / 2}, y \in \mathbb{F}_{2}^{n / 2} \backslash\{x\}}}(-1)^{f(x, y)}\left((-1)^{a x+b y}-(-1)^{a y+b x}\right)\right| \\
& =\frac{1}{2}\left|\sum_{\substack{x \in \mathbb{F}_{2}^{n / 2}, y \in \mathbb{F}_{2}^{n / 2} \backslash\{x\} \\
(x, y) \notin S}} 2(-1)^{f(x, y)+a x+b y}+\sum_{\substack{x \in \mathbb{F}_{2}^{n / 2}, y \in \mathbb{F}_{2}^{n / 2} \backslash\{x\} \\
(x, y) \in S}} 0\right| \\
& \leq \frac{1}{2}\left|2\left(2^{n / 2}\left(2^{n / 2}-1\right)-2^{n-1}+2^{n / 2}\right)\right|=\left|2^{n}-2^{n / 2}-2^{n-1}+2^{n / 2}\right|=2^{n-1}
\end{aligned}
$$

Finally, using the relation between nonlinearity and Walsh transform (Definition 7] we obtain:

$$
\mathrm{NL}(f)=2^{n-1}-\frac{1}{2} \max _{c \in \mathbb{F}_{2}^{n}}\left|W_{f}(c)\right| \geq 2^{n-1}-\frac{1}{2}\left(2^{n-1}+2^{n / 2}\right)=2^{n-2}-2^{n / 2-1}
$$

Theorem 4. Let $m \in \mathbb{N}^{*}, n=2^{m}$ and $f$ be a function from the constructions of Definition 11 or Definition 12 then, for all $k \in[0, n]$ :

$$
\mathrm{NL}_{k}(f) \geq \frac{1}{4}\binom{n}{k}-\binom{\frac{n}{2}}{\frac{k}{2}}-\frac{1}{2} \max _{\ell \in[1, n]}\left|\sum_{t=0}^{k} \mathrm{~K}_{t}\left(\ell, \frac{n}{2}\right) \mathrm{K}_{k-t}\left(\ell, \frac{n}{2}\right)\right| .
$$

Proof. We compute the restricted Walsh transform of $f$ on $\mathrm{E}_{k, n}$. For all $c \in \mathbb{F}_{2}^{n}$ :

$$
\begin{aligned}
\mathcal{W}_{f, k}(c) & =\sum_{z \in \mathrm{E}_{k, n}}(-1)^{f(z)+c z} \\
& =\sum_{x \in \mathrm{E}_{k / 2, n / 2}}(-1)^{f(x, x)+(a+b) x}+\sum_{(x, y) \in \mathrm{E}_{k, n}, x \neq y}(-1)^{f(x, y)+a x+b y} \\
& =\sum_{x \in \mathrm{E}_{k / 2, n / 2}}(-1)^{f(x, x)+(a+b) x}+\sum_{t=0}^{k} \sum_{\substack{x \in \mathrm{E}_{t, n / 2}, y \in \mathrm{E}_{k-t, n / 2} \\
x \neq y}}(-1)^{f(x, y)+a x+b y} \\
& =\sum_{x \in \mathrm{E}_{k / 2, n / 2}}(-1)^{f(x, x)+(a+b) x}+\frac{1}{2} \sum_{t=0}^{k} \sum_{\substack{x \in \mathrm{E}_{t, n / 2}, y \in \mathrm{E}_{k-t, n / 2} \\
x \neq y}}(-1)^{f(x, y)}\left((-1)^{a x+b y}-(-1)^{a y+b x}\right)
\end{aligned}
$$

where $(a, b)=c$, that is $a$ denotes the first $n / 2$ bits of $c$ and $b$ denotes the second half. Similarly, $(x, y)=z$, where $x$ denotes the first $n / 2$ variables of $z$ and $y$ the second half.

Similarly to the proof of Theorem 3, we are looking for the number of elements $(x, y)$ such that $(-1)^{a x+b y}-(-1)^{a y+b x}=0$. This is equivalent to the number of elements $(x, y)$ such that $(a+b)(x+y)=0$ $\bmod 2$ where this time $x \in \mathrm{E}_{t, n / 2}$ and $y \in \mathrm{E}_{k-t, n / 2}$. Denoting $a+b$ as $d$ we have that all elements lead to 0 if $d=0_{n / 2}$, for the other values of $d$ we determine it in function of $\ell=\mathrm{w}_{\mathbf{H}}(d)$ :

$$
\begin{aligned}
\left|S_{d}\right| & =\left|\left\{x \in \mathrm{E}_{t, n / 2}, y \in \mathrm{E}_{k-t, n / 2} \mid(x+y) d=0\right\}\right| \\
& =\left|\left\{x \in \mathrm{E}_{t, n / 2}, y \in \mathrm{E}_{k-t, n / 2} \mid x d=y d=0\right\}\right|+\left|\left\{x \in \mathrm{E}_{t, n / 2}, y \in \mathrm{E}_{k-t, n / 2} \mid x d=y d=1\right\}\right| \\
& =\left|\left\{x \in \mathrm{E}_{t, n / 2} \mid x d=0\right\}\right|\left|\left\{y \in \mathrm{E}_{k-t, n / 2} \mid y d=0\right\}\right|+\left|\left\{x \in \mathrm{E}_{t, n / 2} \mid x d=1\right\}\right|\left|\left\{y \in \mathrm{E}_{k-t, n / 2} \mid y d=1\right\}\right|
\end{aligned}
$$

Then, we determine $\left|\left\{x \in \mathrm{E}_{t, n / 2} \mid x d=0\right\}\right|$ using the definition of Krawtchouk polynomials (Definition 9 ):

$$
\begin{aligned}
\left|\left\{x \in \mathrm{E}_{t, n / 2} \mid x d=0\right\}\right| & =\sum_{\substack{j=0 \\
j \text { even }}}^{t}\binom{\ell}{j}\binom{n / 2-\ell}{t-j} \\
& =\frac{1}{2}\left(\sum_{\substack{j=0 \\
j \text { even }}}^{t}\binom{\ell}{j}\binom{n / 2-\ell}{t-j}+\sum_{j=0}^{t}\binom{\ell}{j}\binom{n / 2-\ell}{t-j}-\sum_{\substack{j=0 \\
j \text { odd }}}^{t}\binom{\ell}{j}\binom{n / 2-\ell}{t-j}\right) \\
& =\frac{1}{2}\left(\mathrm{~K}_{t}(\ell, n / 2)+\sum_{j=0}^{t}\binom{\ell}{j}\binom{n / 2-\ell}{t-j}\right) \\
& =\frac{1}{2}\left(\mathrm{~K}_{t}(\ell, n / 2)+\binom{n / 2}{t}\right)
\end{aligned}
$$

where the last equation comes from the Vandermonde convolution (Property 4). Using similar formulas for the other sets we obtain:

$$
\begin{aligned}
\left|S_{d}\right| & =\frac{1}{4}\left(\binom{\frac{n}{2}}{t}+\mathrm{K}_{t}\left(\ell, \frac{n}{2}\right)\right)\left(\binom{\frac{n}{2}}{k-t}+\mathrm{K}_{k-t}\left(\ell, \frac{n}{2}\right)\right)+\frac{1}{4}\left(\binom{\frac{n}{2}}{t}-\mathrm{K}_{t}\left(\ell, \frac{n}{2}\right)\right)\left(\binom{\frac{n}{2}}{k-t}-\mathrm{K}_{k-t}\left(\ell, \frac{n}{2}\right)\right) \\
& =\frac{1}{4}\left(2\binom{\frac{n}{2}}{t}\binom{\frac{n}{2}}{k-t}+2 \mathrm{~K}_{t}\left(\ell, \frac{n}{2}\right) \mathrm{K}_{k-t}\left(\ell, \frac{n}{2}\right)\right) .
\end{aligned}
$$

Using the value of $\left|S_{d}\right|$ we can derive an lower bound on $\left|\mathcal{W}_{f, k}(c)\right|$ :

$$
\begin{aligned}
& \left|\mathcal{W}_{f, k}(c)\right|=\left|\sum_{x \in \mathrm{E}_{k / 2, n / 2}}(-1)^{f(x, x)+(a+b) x}+\frac{1}{2} \sum_{t=0}^{k} \sum_{\substack{x \in \mathrm{E}_{t, n / 2}, y \in \mathrm{E}_{k-t, n / 2} \\
x \neq y}}(-1)^{f(x, y)}\left((-1)^{a x+b y}-(-1)^{a y+b x}\right)\right| \\
& \leq\binom{ n / 2}{k / 2}+\left|\frac{1}{2} \sum_{t=0}^{k} \sum_{\substack{x \in \mathrm{E}_{t, n / 2}, y \in \mathrm{E}_{k-t, n / 2} \\
x \neq y}}(-1)^{f(x, y)}\left((-1)^{a x+b y}-(-1)^{a y+b x}\right)\right| \\
& \leq\binom{ n / 2}{k / 2}+\left\lvert\, \frac{1}{2} \sum_{t=0}^{k}\left(\sum_{\substack{x \in \mathrm{E}_{t}, \frac{n}{2}, y \in \mathrm{E}_{k-t, \frac{n}{2}}^{x \neq y,(x, y) \in S_{d}}}}(-1)^{f(x, y)}(0)+\sum_{\substack{x \in \mathrm{E}_{t, \frac{n}{2},}, y \in \mathrm{E}_{k-t, \frac{n}{2}} \\
x \neq y,(x, y) \notin S_{d}}} 2(-1)^{f(x, y)+a x+b y) \mid}\right.\right. \\
& \leq\binom{\frac{n}{2}}{\frac{k}{2}}+\left|\frac{1}{2}\left(\sum_{t=0}^{k} 2\left(\binom{\frac{n}{2}}{t}\binom{\frac{n}{2}}{k-t}-\frac{1}{2}\binom{\frac{n}{2}}{t}\binom{\frac{n}{2}}{k-t}-\mathrm{K}_{t}\left(\ell, \frac{n}{2}\right) \mathrm{K}_{k-t}\left(\ell, \frac{n}{2}\right)\right)\right)\right|+\left|\frac{1}{2} 2\binom{\frac{n}{2}}{\frac{k}{2}}\right| \\
& \leq 2\binom{\frac{n}{2}}{\frac{k}{2}}+\left|\sum_{t=0}^{k}\left(\frac{1}{2}\binom{\frac{n}{2}}{t}\binom{\frac{n}{2}}{k-t}-\mathrm{K}_{t}\left(\ell, \frac{n}{2}\right) \mathrm{K}_{k-t}\left(\ell, \frac{n}{2}\right)\right)\right| \\
& \leq 2\binom{\frac{n}{2}}{\frac{k}{2}}+\frac{1}{2}\binom{n}{k}+\left|\sum_{t=0}^{k} \mathrm{~K}_{t}\left(\ell, \frac{n}{2}\right) \mathrm{K}_{k-t}\left(\ell, \frac{n}{2}\right)\right|,
\end{aligned}
$$

where the last equation comes from the Vandermonde convolution (Property 4 .

Finally, we can give the bound on the $\mathrm{NL}_{k}$ using the relation with the restricted Walsh transform:

$$
\begin{aligned}
\mathrm{NL}_{k}(f) & =\frac{1}{2}\binom{n}{k}-\frac{1}{2} \max _{c \in \mathbb{F}_{2}^{n}}\left|\mathcal{W}_{f, k}(c)\right| \\
& \geq \frac{1}{2}\binom{n}{k}-\frac{1}{2} \max _{\ell \in[1, n]}\left(2\binom{\frac{n}{2}}{\frac{k}{2}}+\frac{1}{2}\binom{n}{k}+\left|\sum_{t=0}^{k} \mathrm{~K}_{t}\left(\ell, \frac{n}{2}\right) \mathrm{K}_{k-t}\left(\ell, \frac{n}{2}\right)\right|\right) \\
& \geq \frac{1}{4}\binom{n}{k}-\binom{\frac{n}{2}}{\frac{k}{2}}-\frac{1}{2} \max _{\ell \in[1, n]}\left|\sum_{t=0}^{k} \mathrm{~K}_{t}\left(\ell, \frac{n}{2}\right) \mathrm{K}_{k-t}\left(\ell, \frac{n}{2}\right)\right| .
\end{aligned}
$$

## 4 Concrete constructions and parameters

### 4.1 WPB from popular orders

We can take different orders to compare the properties reached in practice by the construction of Definition [11. For example we will consider the orders lexicographic and cool [SW12]. For these two cases we use the lexicographic order (respectively cool order taking 0 as the first element) to define the orders on the $2^{i}$-length binary strings for $i \in[0, m-1]$. We give the properties of the produced WPB functions in 8 and 16 variables in Table 1 and Table 2, (in our code the binary strings are encoded a integer, considering the least significant bit in position $n$ ).

We observe that most of the parameters of the function given by the cool order are better than than the one given by the the lexicographic order. The algebraic immunity of the construction from the lexicographic order is the minimal possible for a WPB function in more than 2 variables (see [GM23a], Theorem 1). In the following proposition we show that any WPB function $f$ built from Definition 11 or Definition 12 with the lexicographic order as $\prec_{m-1}$ has AI only 2 .

| Function | res | $\operatorname{deg}$ | NL | AI | $\mathrm{NL}_{2}$ | $\mathrm{NL}_{3}$ | $\mathrm{NL}_{4}$ | $\mathrm{NL}_{5}$ | $\mathrm{NL}_{6}$ | $\mathrm{AI}_{2}$ | $\mathrm{AI}_{3}$ | $\mathrm{AI}_{4}$ | $\mathrm{AI}_{5}$ | $\mathrm{AI}_{6}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

Table 2. Cryptographic parameters of Construction 1 in 8 variables instantiated with the lexicographic order (Lex) and the cool order (Cool)

Proposition 3. Let $m \in \mathbb{N}, m \geq 2$, and $f$ be a Boolean function from Construction 1 with the lexicographic order as $\preceq_{m-1}$ or Construction 2 with the lexicographic order as $\preceq$, then $f$ satisfies:

$$
\mathrm{Al}(f)=2, \quad \text { and } \quad \forall k \in\left[1,2^{m}-1\right] \mathrm{Al}_{k}(f) \leq 2 .
$$

Proof. First we show the result on the algebraic immunity. We denote each input of $\mathbb{F}_{2}^{2^{m}}$ as $(x, y)=$ $\left(x_{1}, \ldots, x_{r}, y_{1}, \ldots, y_{r}\right)$, where $r=2^{m-1}$. When $x \neq y$ both constructions use the lexicographic order on $x$ and $y$ to determine the output. By definition of the lexicographic order (Definition 8), if $x_{1}=1$ and $y_{1}=0$ then $y \preceq x$ and $f(x, y)=1$, if $x_{1}=0$ and $y_{1}=1$ then $x \preceq y$ and $f(x, y)=0$. Then, the function $g(x, y)=\left(x_{1}+y_{1}\right)\left(1+x_{1}\right)=x_{1} y_{1}+y_{1}$ is non null and an annihilator of $f$. Finally, since $\operatorname{deg}(g)=2$ and the algebraic immunity of a WPB function in more than 2 variables is at least 2 ([GM23a], Theorem 1), it gives the algebraic immunity of $f$.

Regarding the weightwise algebraic immunity, we show that the function $g$ is not constant on $\mathrm{E}_{k, 2^{m}}$ for $k \in\left[1,2^{m}-1\right]$, therefore it is also a non null annihilator of $f$ on the slice, implying $\mathrm{Al}_{k}(f) \leq 2$. We focus on the values taken by $x_{1}$ and $y_{1}, g$ takes the value 1 when $x_{1}=1+y_{1}=0$ and the value 0 when $x_{1}=1+y_{1}=1$. Therefore, using an element ( $x^{\prime}, y^{\prime}$ ) of Hamming weight $k-1$ (for each k ) to instantiate the $2^{m}-2$ other variables, we obtain $\left(0, x^{\prime}, 1, y^{\prime}\right) \in \mathrm{E}_{k, 2^{m}}$ and $\left(1, x^{\prime}, 0, y^{\prime}\right) \in \mathrm{E}_{k, 2^{m}}$ such that $g\left(0, x^{\prime}, 1, y^{\prime}\right) \neq g\left(1, x^{\prime}, 0, y^{\prime}\right)$ hence $g$ is not constant on $\mathrm{E}_{k, 2^{2}}$. It allows us to conclude $\mathrm{Al}_{k}(f) \leq 2$.

The Proposition 3 can be extended to other orders than the lexicographic one, such as reverse lexicographic. Indeed, if for $\preceq_{m-1}$ or $\preceq$ there is one position $i$ such that $f(x, y)=1+f\left(x+e_{i}, y+e_{i}\right)$ (where $e_{i}$ denotes the vector having a one only in position $i$ ) when $x_{i} \neq y_{i}$ then the same reasoning applies, and the function admit a degree two annihilator.

The properties of the functions given in Table 2 are low, compared for example with $h_{16}$ in [GM22b] which has degree 14, AI 8 , and better nonlinearities. In the next part we study different orders leading to better degree and algebraic immunity.

### 4.2 WPB from weightwise orders

In this part we consider the notion of weightwise order, that is, an order $\preceq$ that satisfies for all $x \in \mathbb{F}_{2}^{n}$ and $y \in \mathbb{F}_{2}^{n}$ if $w(x)<w(y)$ then $x \prec y$. Note that the graded lexicographic order is an example of weightwise order.

First we show that any function built using Construction 1 with a weightwise order for $\preceq_{m-1}$ or Construction 2 with a weightwise order as $\preceq$ has optimal algebraic immunity. Then, we show that these WPB functions are a (strict) subset of TL functions. Finally, we give the parameters of 2 such functions in 8 and 16 variables.

Proposition 4. Let $m \in \mathbb{N}, m \geq 2$, and $f$ be a Boolean function from Construction 1 with a weightwise order as $\preceq_{m-1}$ or Construction 2 with a weightwise order as $\preceq$, then $f$ satisfies:

$$
\operatorname{Al}(f)=2^{m-1}
$$

Proof. The proof consists in showing that $f$ belongs to the TL family of WPB functions, hence Property 5 allows to conclude its algebraic immunity is $2^{m-1}$.

We use the characterization of TL functions given in Definition 10, we use the notation $n=2^{m}$ for simplicity. The first property $f\left(0_{n}\right)=0$ and $f\left(1_{n}\right)=1$ is true since $f$ is WPB by Theorem 1 (respectively Theorem 2 for Construction 2). The properties $f(x, y)=0$ if $\mathrm{w}_{\mathrm{H}}(x)<\mathrm{w}_{\mathrm{H}}(y)$. and $h(x, y)=1$ if $\mathrm{w}_{\mathrm{H}}(x)>$
$\mathrm{w}_{\mathrm{H}}(y)$ are respected since $f$ is build with a weightwise order. The last property to check is: $\forall j \in\left[1,2^{m-1}-\right.$ $1]$, $\operatorname{supp}(f) \cap A_{j}=\left|A_{j}\right| / 2$, where $A_{j}=\left\{(x, y) \in \mathbb{F}_{2}^{2^{m-1}} \times \mathbb{F}_{2}^{2^{m-1}}: \mathrm{w}_{\mathrm{H}}(x)=\mathrm{w}_{\mathrm{H}}(y)=j\right\}$.

If $f$ is from Construction 1 , we have that for all $x$ and $y$ such that $x \neq y$ only one of the two elements between $(x, y)$ and $(y, x)$ is in the support of $f$. For the elements $(x, x)$ such that $x \in \mathbb{F}_{2}^{m-1} \backslash\left\{0_{2^{m-1}}, 1_{2^{m-1}}\right\}$ the value of $f$ is defined by $f_{m-1}$ which is WPB by Theorem 1 hence over all $x$ of Hamming weight $j$, half are in the support of $f_{m-1}$ and therefore half of the elements $(x, x)$ are in the support of $f$. It allows to conclude supp $(f) \cap A_{j}=\left|A_{j}\right| / 2$, hence $f$ is a TL function.

If $f$ is from Construction 2, as before we have that for all $x$ and $y$ such that $x \neq y$ only one of the two elements between $(x, y)$ and $(y, x)$ is in the support of $f$. For the elements $(x, x)$ such that $x$ has Hamming weight $j$, by definition of the order $\preceq^{\prime}$ (in Definition 12), $f$ takes the value 0 for half of the values and 1 on the other half. It allows to conclude $\operatorname{supp}(f) \cap A_{j}=\left|A_{j}\right| / 2$, therefore $f$ is a TL function.

Remark 2. In the proof of Proposition 4, the AI is derived from the membership to the TL family. The functions considered in that proposition are a strict subset of the TL family. For two different elements of $\mathbb{F}_{2}^{m-1}$ with the same Hamming weight, say $x$ and $y$, only one of the two elements between $(x, y)$ and $(y, x)$ can be in the support of an order-based WPB function. Conversely, there are TL functions such that $(x, y)$ and $(y, x)$ are both in the support or in the co-support since $m \geq 2$ (see Definition 10 .

Table 4. Cryptographic parameters of Construction 1 in 16 variables instantiated with the weightwise lexicographic order (HWlex) and weightwise cool order (HWcool).

Both functions with parameters displayed in Table 3 and Table 4 have better degree and algebraic immunity than the one from Section 4.1. Regarding nonlinearity and weightwise nonlinearities, the values are similar or worse.

We also remark that for $k$ odd any WPB function produced with a weightwise order with Construction 1 or Construction 2 will have $\mathrm{NL}_{k}$ and $\mathrm{NL}_{n-k}$ equal. This comes from the fact that for these values of $k$
the two parts $x$ and $y$ cannot have the same Hamming weight, then $f$ takes the opposite value on $(x, y)$ and $(x, y)+1_{2^{m}}$ for all $(x, y) \in \mathrm{E}_{k, n}$. Therefore, the distance between an affine function $a(x, y)+\varepsilon$ and $f$ over $\mathrm{E}_{k, n}$ is the same as the one between $a\left((x, y)+1_{2^{m}}\right)+\varepsilon+1$ and $f$ over $\mathrm{E}_{n-k, n}$. Regarding the case $k$ even, $x$ and $y$ can have the same Hamming weight, and it this case the relation between $f(x, y)$ and $f\left((x, y)+1_{2 m}\right)$ is not constant.

For a similar reason, the WPB function built recursively with the lexicographic order (Lex in Table 1 and Table 2) has the same weightwise nonlinearity on $\mathrm{E}_{k, n}$ and $\mathrm{E}_{n-k, n}$. The lexicographic order corresponds to the natural order in $\mathbb{Z}$ identifying $u \in \mathbb{F}_{2}^{t}$ to the integer $u^{\prime}=\sum_{i=1}^{t} 2^{i-1} u_{i}$, therefore $u \prec v$ corresponds to $u^{\prime}<v^{\prime}$ and since $\tilde{u}=u+1_{2^{t}}$ corresponds to $2^{t}-u^{\prime}$, we have $u^{\prime}<v^{\prime}$ implies $2^{t}-u^{\prime}>2^{t}-v^{\prime}$ therefore $\tilde{v} \prec \tilde{u}$. Accordingly, $f(x, y)+f\left((x, y)+1_{2 m}\right)$ is constant for all weight of $(x, y)$ for this function, leading to $\mathrm{NL}_{k}(f)=\mathrm{NL}_{n-k}(f)$.

### 4.3 Orders from a field representation

We consider orders that come from a different representation of $\mathbb{F}_{2}^{n}$, as it has been fruitful to build Boolean function with optimal algebraic immunity. Various constructions using the univariate representation [CF08, Riz10, ZCSH11, LCZ $^{+}$14] (as functions from $\mathbb{F}_{2^{n}}$ to $\mathbb{F}_{2}$ ) or modifications of these constructions [LKK13, LK18], give families with optimal algebraic immunity and other good cryptographic properties such as high algebraic degree and good nonlinearity. The Carlet-Feng construction for example identifies $\mathbb{F}_{2}^{n}$ to $\mathbb{F}_{2^{n}}$ and for $\alpha$ a primitive element of $\mathbb{F}_{2^{n}}$, the function $f$ is defined by its support: 0 and $\alpha^{i}$ for $i \in\left[0,2^{n-1}-2\right]$. Similarly, we identify $\mathbb{F}_{2}^{r}$ to $\mathbb{F}_{2^{r}}$ and define the order using the consecutive powers of $\alpha$, as in the following definition:

Definition 13 (field order). Let $r \in \mathbb{N}^{*}$, for $s \in \mathbb{N}$ such that $s \leq 2^{r}-2$ and $\alpha$ a primitive element of $\mathbb{F}_{2}^{r}$, we call field order defined by $\alpha$ and sthe total order over $\mathbb{F}_{2}^{r}$ given by:

$$
\alpha^{s} \prec \alpha^{s-1} \prec \ldots \prec \alpha^{2^{r}-2} \prec 0 \prec 1 \prec \ldots \prec \alpha^{s-2} \prec \alpha^{s-1} .
$$

For WPB functions we use field orders for $r$ powers of two only. In Table 5 we give the parameters of some 8 -variable WPB functions obtained from the field representation. For these experiments (using Sage math) we took $\alpha$ the root of $X^{4}+X+1$ to build $\mathbb{F}_{16}$ and $\beta$ the root of $X^{2}+X+1$ to build $\mathbb{F}_{4}$. The value $t$ corresponds to the choice for the order used on the binary strings of length 2 , and $s$ for the one of length 4. We give the parameters of all 8 -variable WPB functions of this family in Appendix 7, in Table 10 and Table 11

Table 6. Cryptographic parameters of Construction 1 in 16 variables instantiated with the field representation.

From Table 5 and Table 6 we observe that the obtained functions have optimal degree ( $n-1$ for a balanced function) and optimal algebraic immunity ( $\lceil n / 2\rceil$ ). Their weightwise algebraic immunities are at least as good as the ones of the functions built in Section 4.1 and Section 4.2 , with a neat improvement for the medium weights in 16 variables. We display in green the values that reach the upper bound on the weightwise algebraic immunity $\min \left\{e \in \mathbb{N} \left\lvert\, 2\binom{n}{e}>\binom{n}{k}\right.\right\}$ ([CMR17], Corollary 9), we observe that the weightwise AI of the function we test are optimal on the medium weights (from 6 to 10) in 16 variables. Regarding the nonlinearity and weightwise nonlinearities, in 8 variables there is always a function from Table 5 with a better value than the functions with parameters exhibited in Section 4.1 and Section 4.2. In 16 variables, the 3 WPB functions with parameters displayed in Table 6 always have better nonlinearity and weightwise nonlinearities than the other functions. The experimental findings suggest that utilizing orderbased construction with field representations stands out as a very promising approach for generating WPB functions with good cryptographic parameters.

## 5 Generalization to WAPB constructions

In this section we generalize the recursive order-based construction to build WAPB functions, and we exhibit the parameters of some of them. There are a few secondary constructions available for building WAPB functions as illustrated in [ZS22, GM22b]. However, most constructions are primarily focused on WPB functions and do not extend to WAPB functions.

### 5.1 An order-based WAPB construction

We propose the following construction of WAPB functions for any value of $n$ (greater than 1 ).
Definition 14 (Construction 3). Let $n \in \mathbb{N}, n \geq 2$ and for $i \in\left[1,\left\lfloor\log _{2}(n)\right\rfloor\right] \preceq\left\lfloor n /\left(2^{i}\right)\right\rfloor$ be a total order on the set of $\left\lfloor n /\left(2^{i}\right)\right\rfloor$-length binary string.

Let $f_{n}$ be the $n$-variable function defined recursively as:

- if $n=1, f_{1}(0)=0$ and $f_{1}(1)=1$,
- if $n$ is odd, $f_{n}\left(x_{1}, \ldots, x_{n}\right)=f_{n-1}\left(x_{1}, \ldots, x_{n-1}\right)$

$$
f_{n}(x, y)= \begin{cases}f_{\lfloor n / 2\rfloor}(x) & \text { if } x=y \\ 0 & \text { if } x \prec_{n / 2} y \\ 1 & \text { if } y \prec_{n / 2} x\end{cases}
$$

where $x, y \in \mathbb{F}_{2}^{n / 2}$.
Theorem 5. Let $f_{n}$ defined as in Definition $14 f_{n}$ is weightwise almost perfectly balanced.
Proof. We prove the result by recursion. First, if $n=1, f_{1}(0)=0$ and $f_{1}(1)=1$ hence $f_{1}=x_{1}$ is WAPB by definition. Then, we assume that $f_{i}$ is WAPB for all $i \in[1, n-1]$ such that $f_{i}$ is defined. We consider two cases, $n$ odd and $n$ even.

If $n$ is odd, by construction $f_{n}\left(x_{1}, \ldots, x_{n}\right)=f_{n-1}\left(x_{1}, \ldots, x_{n-1}\right)$. In this case $f_{n}$ can be written using Siegenthaler's construction as:

$$
f_{n}=x_{n} \cdot f_{n-1}\left(x_{1}, \ldots, x_{n-1}\right)+\left(1+x_{n}\right) \cdot f_{n-1}\left(x_{1}, \ldots, x_{n-1}\right) .
$$

Using [GM22b] Proposition 2 we have the following relation on the restricted Walsh transform of $f_{n}$ for all $k \in[0, n]$ :

$$
\mathcal{W}_{f_{n}, k}\left(0_{n}\right)=\mathcal{W}_{f_{n-1}, k}\left(0_{n}\right)+\mathcal{W}_{f_{n-1}, k-1}\left(0_{n}\right) .
$$

Using Property 1 since $f_{n-1}$ is WAPB we have that both $\mathcal{W}_{f_{n-1}, k}\left(0_{n}\right)$ and $\mathcal{W}_{f_{n-1}, k-1}\left(0_{n}\right)$ have absolute value no greater than 1 . Since $n-1$ is even, at least one of the binomial coefficients between $\binom{n-1}{k}$ and $\binom{n-1}{k-1}$ is even $\left(\binom{m}{r}\right.$ with $m$ even and $r$ odd is even using Lucas' theorem), hence $\mathcal{W}_{f_{n}, k}\left(0_{n}\right) \in\{-1,0,1\}$, and $f_{n}$ is WAPB by Property 1 .

If $n$ is even, we rewrite $\mathcal{W}_{f_{n}, k}\left(0_{n}\right)$ :

$$
\mathcal{W}_{f_{n}, k}\left(0_{n}\right)=\mathcal{W}_{f_{n}, A}\left(0_{n}\right)+\mathcal{W}_{f_{n}, B}\left(0_{n}\right),
$$

where $A=\left\{\mathrm{E}_{k, n} \cap\left\{(x, y), x \in \mathbb{F}_{2}^{n / 2}, y \in \mathbb{F}_{2}^{n / 2}, x=y\right\}\right\}$ and $B=\left\{\mathrm{E}_{k, n} \cap\left\{(x, y), x \in \mathbb{F}_{2}^{n / 2}, y \in\right.\right.$ $\left.\left.\mathbb{F}_{2}^{n / 2}, x \neq y\right\}\right\}$. Since $f_{\lfloor n / 2\rfloor}(x)=0$ if $x \prec_{n / 2} y$ and 1 if $y \prec_{n / 2} x$, we get $W_{f_{n}} B\left(0_{n}\right)=0$. Then, note that $W_{f_{n}} A\left(0_{n}\right)=W_{f_{n / 2}} \frac{n}{2}\left(0_{n / 2}\right)$, and since $f_{n / 2}$ is WAPB by assumption, $W_{f_{n / 2}} \frac{n}{2}\left(0_{n / 2}\right) \in\{-1,0,1\}$ hence $W_{f_{n}} k\left(0_{n}\right) \in\{-1,0,1\}$ which allows to conclude that $f_{n}$ is WAPB in this case and it finishes the proof.

Remark 3. Note that when $\mathrm{E}_{k, n}$ has an odd parity the value of -1 or +1 of $\mathcal{W}_{f, k}$ circles back to the values of $f_{1}$, which leads to having one extra 0 for slices such that $k<n / 2$ and an extra 1 for $k>n / 2$. Accordingly, the functions generated by Construction 3 are Special WAPB functions (as introduced in [GM22b]).

We also remark that for $m$ a power of 2 , the functions created are the same WPB functions as the ones built from Construction 1 (only the index of the orders differ, between 0 and $m-1$ for Construction 1 corresponding to $2^{0}$ to $2^{m-1}$ for Construction 3).

Note also that Construction 3 can be generalized to give other WAPB functions. Defining $f_{n}\left(x_{1}, \ldots, x_{n}\right)$ as $f_{n-1}\left(x_{1}, \ldots, x_{n-1}\right)$ when $n$ is odd corresponds to ignoring the last variable to keep even-length bitstrings, it allows to consider an order comparing the two (same-length) halves. Similarly, any of the $n$ variables can be ignored at each step where $n$ is odd, giving different WAPB constructions. Additionally the values of $f$ in $0_{n}$ and $1_{n}$ can also be defined differently at each step to generalize the construction.

### 5.2 Order-based WAPB construction and experimental results

In this section, we present the parameters of WAPB functions derived from Construction 3, based on orders previously outlined in Section 4. Notably, for an odd number $n$, the function $f_{n}$ is equivalent to $f_{n-1}$ but includes an additional mute variable. Consequently, the characteristics of $f_{n}$ can be deduced from those of $f_{n-1}$ (for instance, by applying the properties related to the direct sum of $f_{n-1}$ and the 1 -variable null
function, see for example [MJSC16] Lemma 3). Therefore, our analysis primarily concentrates on functions with an even number of variables. Detailed parameters for WAPB functions with 10 variables are provided in Table 7 . Subsequently, we delve into the functions with 12 variables in Table 8 and those with 14 variables in Table 9

In the referenced tables, "Lex" denotes the lexicographic order applied in Construction 3 across various lengths: $1,2,5$ for $n=10 ; 1,3,6$ for $n=12$; and $1,3,7$ for $n=14$. "Cool" signifies the Cool order, detailed in Definition 8. The terms "HWLex" and "HWCool" are used for weightwise orders as described in Section 4.2 "Fields0" and "FieldsHalf" represent the field orders outlined in Definition 13, where for the biggest length, the order is determined with $s=0$ or $s=2^{n / 2-1}$ respectively, with 0 used for the remaining lengths.

Table 9. Cryptographic parameters of Construction 3 in 14 variables instantiated with different orders.

The outcomes for WAPB functions mirror those observed in the previous section for 8 -variable and 16 -variable WPB functions. We note that across various cryptographic parameters, WAPB functions utilizing field-based ordering achieve superior outcomes, particularly in terms of nonlinearities and algebraic immunities. Specifically, the two field-based constructions significantly outperform others in nonlinearity and weightwise nonlinearities, followed by those based on the Cool order, which in turn exhibit better parameters than the remaining constructions. To the best of our knowledge, no other studies have presented parameters for WAPB constructions in more than 8 variables, making it difficult to compare the values reached by these functions beyond between themselves. In terms of algebraic properties, the degree and algebraic immunity for the "Fields0" and "FieldsHalf" constructions are consistently optimal. Highlighted in green are the values that achieve the upper bound of the weightwise algebraic immunity, indicating that, particularly for mid-range weights, the field-based functions reach the optimum. It is important to note that this upper bound may not always be attainable, suggesting that other values presented in the tables could also be optimal.

## 6 Conclusion

In this article, we presented two WPB constructions and one WAPB construction based on the concept of order. Unlike previous approaches for constructing these functions, we anticipate that these W(A)PB functions will be easier to implement and will lead to more efficient computations when used in the context of stream ciphers. Indeed, the ease of implementation and efficiency largely depend on how effectively the order between two inputs, $x$ and $y$, can be determined. This, in turn, hinges on the orders chosen to define the function

In this article, we first demonstrated the general properties of order-based WPB functions. We introduced two constructions: a recursive one that utilizes multiple orders (one for each power of 2 up to $n / 2$ ), and a second one that employs only two orders. We then counted the WPB functions in these two families
and examined their nonlinearities. Specifically, we provided a lower bound for the nonlinearity and the weightwise nonlinearities for all functions within these two families.

Subsequently, we concentrated on specific orders that are commonly used: lexicographic and cool. We also examined weightwise orders, as well as those based on field representation. We demonstrated that within these constructions, some functions, such as those using the lexicographic order, exhibit the lowest possible algebraic immunity. Conversely, all functions employing weightwise orders achieve optimal algebraic immunity.

We provided experimental results detailing the parameters of WPB functions in 8 and 16 variables, along with WAPB functions for $n \in\{10,12,14\}$. We presented the outcomes for global parameters-such as resilience order, nonlinearity, degree, and algebraic immunity-as well as weightwise parameters, specifically $\mathrm{NL}_{k}$ and $\mathrm{Al}_{k}$. This more comprehensive experimental study illustrates that order-based $\mathrm{W}(\mathrm{A}) \mathrm{PB}$ functions can possess robust cryptographic parameters. Notably, those based on field orders exhibit optimal degree, strong algebraic immunity, and favorable weightwise algebraic immunities and nonlinearities.

We outline two open questions arising from this work:

- The bound on nonlinearity from Theorem 3 assures that these functions achieve a nonlinearity that is at least half that of bent functions. It would be interesting to determine if a better bound could be established for the entire family or for a specific subfamily of order-based WPB functions.
- In the tables presented in Sections 4.3 and 5, we highlight instances where functions based on field orders achieve the upper bound of the $\mathrm{Al}_{k}$ parameter. This parameter may be optimal for additional values of $k$, given that the upper bound is not proven to be tight. Further investigation into this criterion is warranted, as currently, very little is known about this variant of algebraic immunity. To date, the values achieved by W(A)PB functions have only been exhibited in a limited number of studies, such as [TL19 GM23b].
